EXECUTIVE SUMMARY

Mine subsidence, the sinking of the ground surface after the collapse of an underground mine, can take place gradually over a large area, or can be quite sudden, opening as a pit at the surface. This ground movement can result in damage to overlying structures and loss of property value. In Illinois, mine subsidence has occurred over all types of underground mines. Most subsidence events are related to coal mines because of the large number and area underlain by coal mines. The largest known subsidence event, however, was over a lead and zinc mine.

This study provides statistics on the proximity of underground-mined areas to urban development. These statistics provide the most detailed view to date of the exposure of structures to the risk of mine subsidence. Prior to this study maps of the non-coal underground mines had never been compiled into a single map database and the proximity of underground-mined areas (both coal and non-coal) to urban development had never been examined. The project was divided into two tasks: 1) to compile a map database of non-coal underground mines, and 2) to provide data on the proximity of both coal and non-coal underground mines to urban development.

Three zones of land area were defined in this study. Two zones were used to indicate the proximity of an area to an underground mine. Zone 1 delineates areas that are over or immediately adjacent to areas that are believed to be undermined. Zone 2 consists of the area adjacent to Zone 1 which may also be affected by subsidence because of uncertainties in the location of the mine. The third zone defined was a one-mile zone around urban areas. This zone, referred to as the urban buffer, locates areas where underground mines (Zones 1 and 2) are near urban areas and may affect future urban expansion.

The final report documents the procedures and assumptions used to complete these tasks and provides an overview of some of the findings. The product of primary interest to the Illinois Mine Subsidence Insurance Fund (IMSIF) is a tabulation by township showing acreage and number of housing units in Zones 1 and 2 (Appendix 1). Maps showing the location of mines and urban areas in each county are provided in Appendix 2. This appendix also includes bar charts depicting the estimated number of housing units in Zone 1 in each township and the acreage of various land use categories in Zone 1 in each county.

Results show that the exposure of urban areas to mine subsidence is not directly proportional to the total acreage mined-out in a county. Of the 77 counties with underground mines, 53 had a higher percentage of urban acreage exposed to mine subsidence than the percentage of mined-out acreage in the whole county. Seven counties had more than 10,000 housing units in Zone 1. Sangamon and St. Clair Counties had the largest number of units in Zone 1 with about 37,600 and 33,900 units respectively. Statewide it was estimated that Zone 1 contains about 229 thousand housing units and Zone 2 contains about 91 thousand housing units.

INTRODUCTION

Mine subsidence, the sinking of the ground surface after the collapse of an underground mine, can take place gradually over a large area, or can be quite sudden, opening as a pit at the surface (DuMontelle et al., 1981). This ground movement may result in damage to overlying structures and loss of property value. In Illinois, mine subsidence has occurred over all types of underground mines. Most subsidence events are related to coal mines because of the large number and area underlain by coal mines. Two of the largest subsidence events to date, however, have been over lead and zinc mines (Touseull, 1980). More than 2660 underground coal mines have operated in Illinois since 1810; all but 30 are now abandoned. Another 356 underground mines have operated to extract clay, fluorspar, lead, zinc, dolomite, limestone, ganister, and tripoli; all but 10 of these mines are abandoned.

Damage caused by "ground movement" is not insured under conventional property insurance. With the inception of the Mine Subsidence Insurance Act in 1979, Illinois became the second state in the country to pass legislation which assures the availability of insurance protection against mine subsidence damage to structures (Illinois State Geological Survey, 1980). The Illinois Mine Subsidence Insurance Fund (IMSIF) monitors subsidence claims and reimburses private insurance companies for claims paid for mine subsidence damage.

The IMSIF needed information that could be used to evaluate their potential exposure to claims for damage caused by mine subsidence. Initially, the only information available was the percentage of each county undermined by coal mines. This information was of limited value because in some areas mines are directly under urban development while in other areas mines underlie land having no insurable structures, such as water bodies and cropland. This information was also limited because it included only coal mines. No statewide map database of the location and extent of non-coal mines had ever been compiled.

This study was designed to provide IMSIF with more complete data on the exposure of areas to mine subsidence. A statewide map database on non-coal underground mines was compiled and statistics were compiled on the proximity of both coal and non-coal underground mines to urban development. The following sections document the data and methods used to complete these tasks and then provide an overview of the findings. Detailed results of the study are presented in Appendix 1. Maps showing the location of mines and urban areas in each county are provided in Appendix 2. This appendix also includes charts depicting the estimated number of units undermined in each township and the acreage of various land use categories undermined in each county.

STATEWIDE MAP DATABASE OF NON-COAL UNDERGROUND MINES

The goal of the first task of this study was to compile all available information on the location and extent of non-coal underground mines. This information would then be used with an existing database of coal mines in the second task of this project to investigate the proximity of mines to urban areas. The resulting compilation consists of two parts; 1) a digital map database that contains the mine boundaries and/or locations of mine openings and 2) documentation of the sources of information for each mine. The maps and other mine data collected for this task are available for inspection at the Illinois State Geological Survey (ISGS).

Sources of Data

Information was collected for 356 non-coal mines (Table 1). The database on non-coal mines is drawn from maps and other information readily available to the Survey. Cook's 1979 inventory of non-coal mines served as our guide to mines. Mine maps were obtained from a variety of sources including ISGS files, U. S. Bureau of Mines, and mining companies. Because state and federal laws have not required companies to file mine maps with the government maps that showed the extent of mine workings were available for only about 20 percent of the mines. Furthermore, some of the maps available were not final mine maps and may not show the complete extent of the mine workings. Locations for the mines lacking maps were obtained from reports, field notes, and topographic maps. The "Documentation of Uncertainties" section of this report explains how incomplete mine information was handled.

Original mine maps were the preferred source for the compilation and digitizing of mine boundaries. We found maps that varied from page-size to wall-size and were drawn on paper (sometimes folded), linen, and tracing paper. Some maps had no scale or reference points. Other maps had incomplete mine boundaries or boundaries that were drawn before mining operations ceased.

Mine maps and mine locations were also obtained from microfilm, publications and other maps. Hard copy prints of original mine maps were made from microfilm of original mine maps acquired through the Federal Office of Surface Mining. Large maps were divided onto two or more microfilm frames and prints were taped together. Locations for mines with no available map were taken from maps and legal descriptions in publications and from shaft and mine tunnel symbols on United States Geological Survey (USGS) 7.5-minute quadrangles. Of all the maps used for compilation (29 different scales of maps, ranging from 1:120 to 1:63,360), the majority of maps were at the scales of 1:2400, 1:4800, and 1:24,000.

Additional information on non-coal mines (beyond the scope of this study) might be obtained through an exhaustive data collection effort involving searches of records in county court houses, libraries, and historical societies, interviews with local citizens, field inspections, and attempts to trace

##the total for fluorspar includes 1 mine that also mined lead.

company ownership. However, the expense of such an effort is probably only justifiable in areas where there is conflict between current urban development and past mining activities.

Method of Compilation

The development of a map database on non-coal mines involved two problems: 1) compilation of mine outlines and mine shaft locations from source maps having a variety of scales and degrees of cartographic accuracy, and 2) documentation of uncertainties of mine location, orientation, and

configuration to be tracked and properly considered in later modeling. To solve these difficulties and produce a database that could be readily combined with the other data to be used for this project, mine maps were converted (digitized) to a computer-readable form and stored in a computer-based geographic information system (GIS).

Three methods were used to enter the mine locations or outlines into the database: 1) digitizing directly from the mine map, 2) transferring the mine outline to a transparent overlay of a 7.5-minute quadrangle and digitizing the transparency, and 3) using a computer program to convert legal descriptions to map coordinates. Maps in good condition that had at least four reference points (section corners or 1/4-section corners) were digitized directly into the database. About 30 percent of the mines were entered in this manner.

Some mine maps had no section corners, or only one. These mines were digitized along with any landmarks that could be used for orientation (north arrows, roads, railroad tracks, landforms, streams, or mine shafts). The mine outlines and landmarks were plotted at 1:24,000 and overlain on the appropriate USGS 7.5-minute topographic quadrangle map. Using the reference points and features digitized from the original map, the mine outline was registered to the topographic map and transferred by hand onto transparent overlays. Mines that were too narrow to digitize as polygons were drawn onto transparencies as lines. Mine shaft and mine tunnel symbols found on quadrangles or other maps were also transferred to the transparencies as point locations. The transparencies were digitized after all mines for that quadrangle were compiled. About 50 percent of the mines were entered in this manner.

When the only information available for a mine was its legal description (township, range, section, quarter section or footages), map coordinates were calculated from the legal description using a computer program and a database of section corner coordinates (Swann et al., 1970). The computed coordinates were entered directly into the non-coal mine database.

Documentation of Uncertainties

Documentation maintained for each mine includes date and source of the maps showing the mine outline or point location, and other sources of information. Possible errors in the source map or compilation process were also recorded. Every mine polygon, line and point entered into the database was assigned a code to indicate the accuracy of the source map and the method used to digitize or enter the data (Table 2). For example, polygons digitized from the original mine maps received a code of 1. Mine locations calculated from a legal description that located the point to the nearest quarter-quarter section were given a code of 8. These location-uncertainty codes were used in the second task of this project to indicate the precision with which the mine was located and to outline the area that could be affected by mine subsidence (Table 2).

Table 2. Non-coal mine location-uncertainty codes and subsidence risk zones.

Code	Source of mine outline or location	Subsidence Zone Width (ft).	
		Zone 1	Zone 2
1	Original mine map, four reference points	500	1000
2	Original mine map, registered using landmarks	500	1000
2	Topographic map	500	1000
4	Map with topography OR with scale larger than 1:24,000	500	1000
5	Map without topography AND scale smaller than 1:24,000	500	2320
6	Legal description with footages or good landmark	500	1000
7	Legal description; section 1/4 1/4 1/4 or CE1/4 or CE1/2 1/4 or CE1/2 or CE1/2 1/2	500	1660
8	Legal description; section 1/4 1/4	500	2320
9	Legal description; section 1/4 or 1/2 1/4	500	3640
10	Legal description; section only	500	6280

EVALUATION OF THE PROXIMITY OF MINES TO URBAN AREAS

The second task of this project was to evaluate the proximity of underground mines (both coal and non-coal) to urban areas. This was accomplished by merging digital maps of the mined areas with digital maps and data on land use and housing. The goal was to produce a tabulation by township listing the estimated acreage of urban land and number of housing units that could be affected by mine subsidence.

The ARC/INFO geographic information system software was used to process the data (Morehouse, 1985). Six spatial data sets and one tabular data set were merged to identify the type of land use and number of housing units that were in areas over or adjacent to underground mines. The GIS provided a mechanism to 1) manage the large volume of data, 2) define zones of risk around mines, 3) adjust and register spatial features from small-scale maps to features from large-scale maps, 4) merge spatial features and link them to the tabular data, and 5) summarize the results in tabular and map form. Technical details of the GIS procedures are provided in Hindman and Treworgy (1989).

Source and Characteristics of Data

An understanding of the source and characteristics of data used in this study is necessary to properly interpret and use the results. The data used for this study came from government agencies and private companies (Table 3) and were collected during the past 20 years. The scale of these data sets makes them ideal for regional applications, but too generalized for site-specific studies. Two important characteristics to be aware of are the minimum size and positional accuracy of features. The minimum size of features depicted in the land use and coal mine data sets is about 10 acres. Features smaller than this are omitted from the land use data set and represented as a point in the coal mine data set. Minimum size was not a factor for the other data sets. The accuracy with which features are located depends, among other factors, on the scale of the source map. Features are generally within 25 feet of their correct location on 1:24,000 scale maps. On 1:250,000 scale maps features may be offset by 250 to 300 feet.

Table 3. Original scale, date and source of digital data.

Data set	Scale of source maps	Date of data	Source of data
Coal mines	1:1200 - 1:62,500	1987	ISGS
Non-coal mines	1:120 - 1:63,360	1988	ISGS
Land use	1:250,000	1969-81	USGS
Census tracts	1:62,500	1980	Geographic Data Technology
Block groups	1:62,500	1988	DENR - county maps
Political townships	1:24,000 - 1:500,000	1984	DENR
Census statistics	tabular data	1980	U. S. Bureau of the Census, and Donnelley Marketing

Coal Mine Data. Data on the location and extent of underground mines were obtained from a digital database maintained by the ISGS (Treworgy et al, 1988). These data were originally compiled in the early 1950's for use in updating estimates of remaining coal resources. The maps are updated periodically to include newly-mined areas. The maps were converted to a digital format in the late 1970's. The original data were compiled on base maps at a scale of 1:62,500 and consisted of a point at the location of the mine entrance and (if available) a polygon outlining the extent of the mined area. All additions and corrections to the database since 1984 have been made using the largest scale source map available (generally 1:4000 to 1:24,000). Unmined blocks

of coal within the mine perimeter are delineated if they cover an area of at least 400 x 400 feet. The mine boundaries used in this project reflect all known mining to January 1987. In some areas this database contains shallow underground mines that have been removed by subsequent surface mining. In all cases these underground mines were small and in non-urban areas. This situation is found in Fulton, Jackson, Knox, Peoria and Stark Counties.

Land Use Data. The land use data used for this study were derived from digital data distributed by the U. S. Geological Survey (Loelkes et al, 1983; Fegeas et al, 1983). The data were compiled from remotely sensed source materials and digitized at a scale of 1:250,000. The data were categorized using the USGS Level I and Level II land classification system. The data for Illinois were collected during the period from 1969 to 1981 and released in digital form in the early 1980's (Table 4).

Table 4. Date of land use from USGS digital files. Map names refer to USGS 1:250,000 series maps.

Census Data

The census data were obtained from the Office of Research and Planning, Illinois Department of Energy and Natural Resources. The tracts, block groups and political townships are map data sets depicting some of the basic geographic subdivisions used in the 1980 census. The census statistics are the actual counts or projections produced by the 1980 census. The block groups and political townships were digitized by or under the sponsorship of the Office of Research and Planning. The tracts and some of the tabular data are proprietary data sets purchased from outside vendors. Other census statistics were from the U.S. Bureau of the Census.

Zones of Mine Subsidence Risk

The risk of mine subsidence of an area is based in part on the proximity of the area to underground mines. The GIS was used to define two zones around mines (Figure 1). Zone 1 delineates the land over or adjacent to mines that, based on the mapped extent of the mine, could be affected by

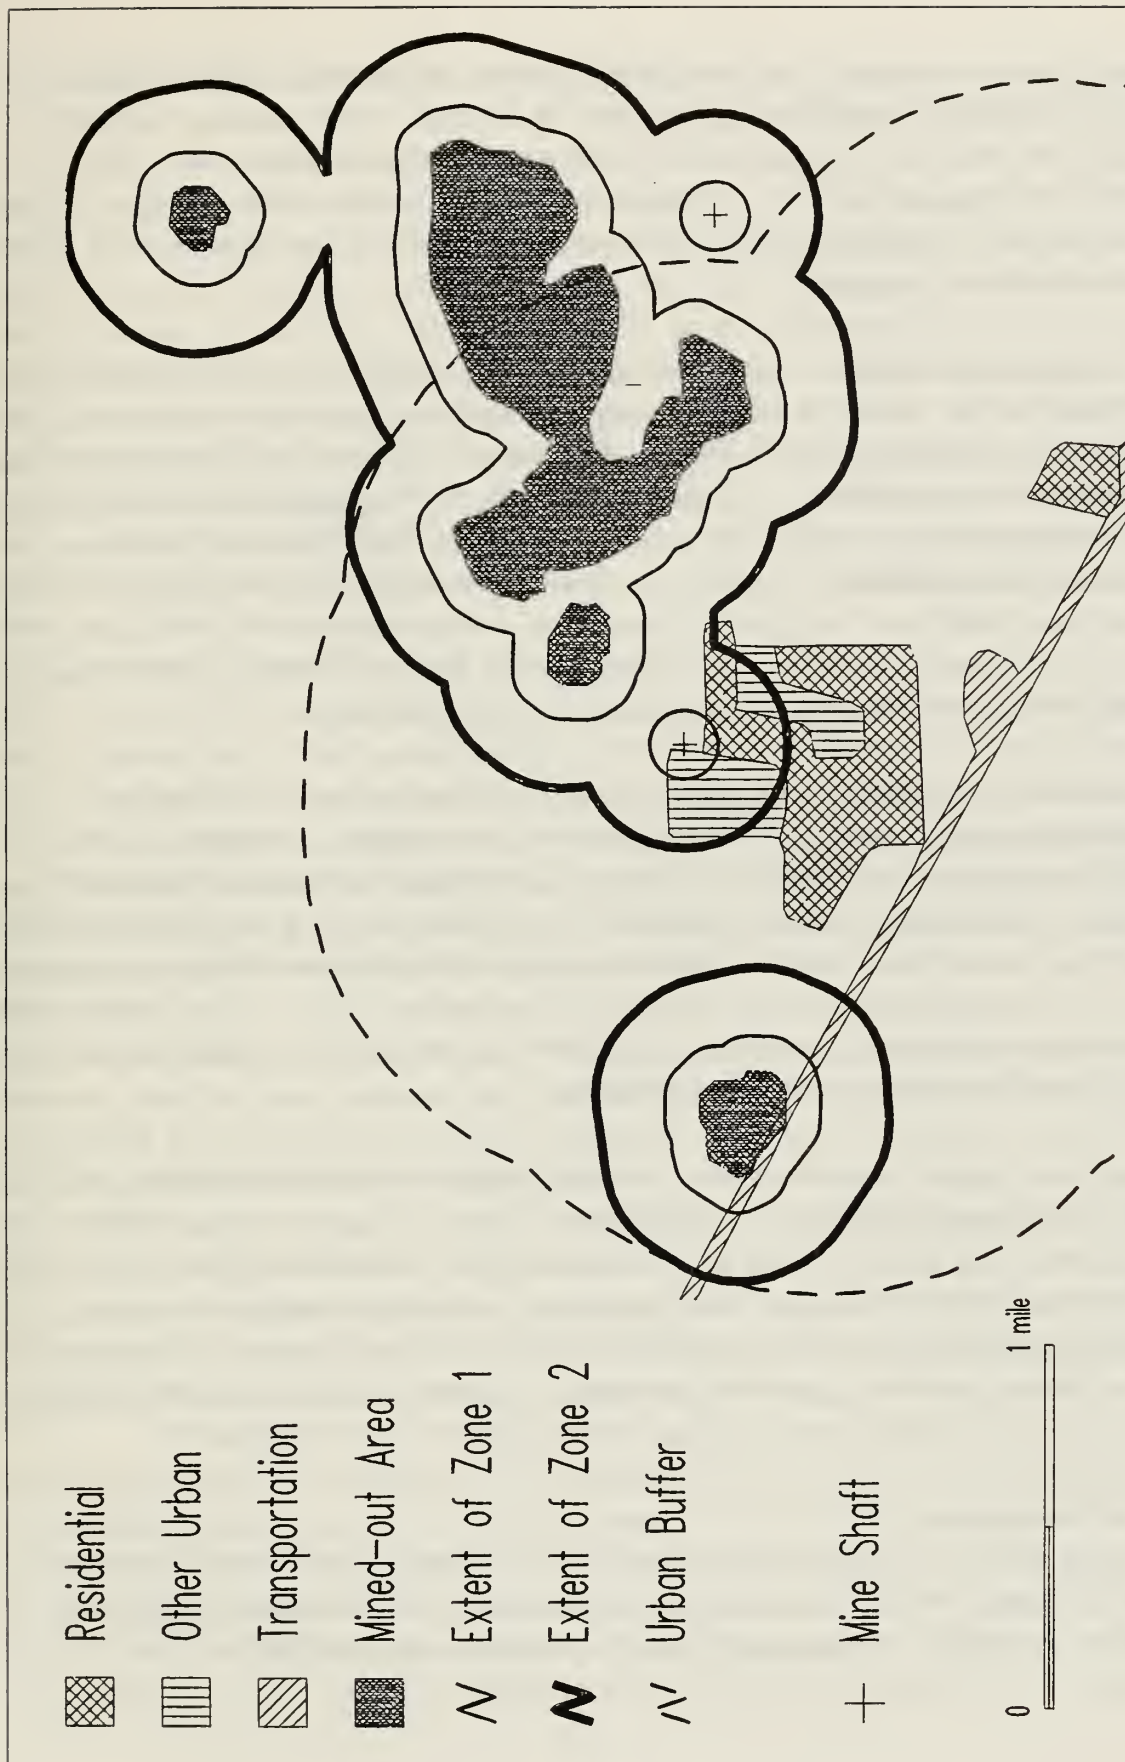

Figure 1. Schematic map showing the relationship of Zones 1 and 2 to mined-out areas and the urban buffer to urban land use.

subsidence. Zone 2 rings Zone 1 and represents additional area that may be affected because of uncertainty in the location of the mine and the extent of workings. Areas outside of these two zones also have some risk of subsidence. Old, undocumented mine openings have been discovered in many parts of the state, even areas not known to contain minable deposits. In most cases however, these undocumented mines were prospect pits or short-term operations that did not undermine more than a few acres.

Zone 1 was defined as the area that is directly over the mapped extent of the mine, and adjacent area extending 500 feet beyond the mine boundary. Land adjacent to a mine was included in this zone because the subsidence from the collapse of an underground mine can spread sideways as it moves upward to the land surface. This lateral ground movement is not highly predictable, but is a function of the depth of the mine, the local geology, and other factors. The distance that subsidence can propagate laterally from a mine is generally much less than the depth of the mine (Bauer and Hunt, 1982). As a conservative measure, we used a distance of 500 feet for all mines. For most mines the lateral propagation of subsidence will be less than 500 feet. Most mines in Illinois and all mines near major urban areas are less than 500 feet deep.

Zone 2 represents areas that were not known to be undermined, but could be affected by subsidence because of uncertainties in the location of mine boundaries. Uncertainties in the positions of mine boundaries come from two sources: 1) incomplete or imprecise maps of mine workings and 2) errors in compilation and digitizing. We estimate that for all coal mines and many non-coal mines the error from these two sources generally would not exceed 1000 feet. For most mines, Zone 2 was defined as the area extending 1000 feet beyond Zone 1. Zone 2 was expanded for non-coal mines located by small-scale maps and for mines with no map according to the size of the area in which the mine might be located (Table 2).

Designation of an area as Zone 1 or Zone 2 cannot be directly translated into subsidence risk. Though the risk of mine subsidence is generally higher in Zone 1 than in the adjacent Zone 2, the risk of subsidence may be low in some areas designated Zone 1 and high in others. Many factors in addition to proximity to a mine have some bearing on the potential for subsidence (e.g. the mining method used, the age of mining, the geology of the overburden, the depth of the mine, previous subsidence, and the depth of the water table). More precise estimates of the risk of subsidence cannot be made until the interaction of these factors is better understood.

Categories of Land Use

Five categories of land use were examined in this study: residential, other urban, urban buffer, non-urban, and water. All but the urban buffer category were based on the land use data set obtained from the USGS. The urban buffer areas were created using the GIS.

The residential category was the same as the residential land use category in the USGS data set and consisted of areas 10 acres or more in size that were predominantly residential. The "other urban" category consisted of the land that the USGS classified as industrial, commercial, industrial and commercial, mixed urban, transportation, and other urban. In some cases the "other urban" category includes land that may not contain structures of concern to IMSIF. For example, a large "other urban" area in Hamilton County is an oil field water flood operation. Some "other urban" areas in Jefferson County are surface facilities of coal mines. Urban areas smaller than 10 acres were not delineated in the USGS data set. The non-urban category consisted of all land that was not urban or water. This included land used for cropland, forest, or pasture. Mines underlying water bodies (rivers, lakes, reservoirs) were not considered a potential source of subsidence damage and excluded from further study. The urban buffer category is a one-mile zone around all urban land areas except the transportation category (Figure 1). This zone was used to identify areas where mines adjacent to urban areas may pose a subsidence risk for future urban expansion.

Number of Housing Units

Data on the number of housing units in a census division were obtained from the 1980 census. Census divisions (tracts, block groups, or enumeration districts depending on the county) were merged with the data on land use and mines to calculate the approximate number homes in Zones 1 and 2. Because the actual distribution of housing units within a census division was not known, these calculations represent estimates, not actual counts of units. These estimates are influenced by assumptions we made on the distribution of housing units and are intended only to provide a general assessment of the exposure of housing units to risk of mine subsidence.

We assumed that within a census division, 90 percent of the housing units would be evenly distributed across the areas classified as residential and the remaining 10 percent of the units would be distributed among all other categories (except water). In divisions that had no areas classified as residential, we assumed units were evenly distributed throughout the area. These assumptions worked well for highly urbanized areas, rural areas with towns, and rural areas with no residential land. In dominantly rural townships with only small areas of residential land this model assigned too many units to the residential areas. For rural townships where the 90/10 distribution of units produced anomalous results, the number of units in Zones 1 and 2 were re-calculated using the assumption that units were evenly distributed across the township.

All of the figures given for housing units in this report are based on the assumption that 90 percent of the housing units in an area are in residential areas. This will obviously not be the case for all townships. To test the sensitivity of our calculations to this assumption, we made a second calculation using the assumption that 75 percent of the units were in residential areas. On a statewide basis the 75/25 distribution calculated 16 percent fewer units in Zone 1 and 10 percent fewer units in Zone 2 than the 90/10 distribution. In 8 percent of the townships there was no

change and in 12 percent of the townships the 75/25 distribution produced an estimate that averaged about 20 percent higher than the 90/10 distribution.

Townships with major towns or cities are of most significance to the focus of this project. We believe the 90/10 distribution produces the best estimate of housing units in these areas.

RESULTS

Examination of the proximity of mined-out areas to urban lands provides a dramatically different view of the potential for mine subsidence from that obtained by merely looking at the total area of a county in Zone 1. Compare, for instance, the ranking of counties by total acreage in Zone 1 to the ranking of counties by the estimated number of housing units in Zone 1 (Table 5). Franklin County was first by a wide margin in total acreage in Zone 1, but had over 24,000 fewer units in Zone 1 than Sangamon County (64 percent fewer). LaSalle County, which ranked 16th in acreage in Zone 1 (less than one-fifth the Zone 1 acreage of Franklin County) ranked ahead of Franklin County in number of units in Zone 1.

Table 5. Ranking of the top 15 counties by total acreage in Zone 1 and the estimated number of housing units in Zone 1.

County	Acreage in Zone 1	County	Housing Units in Zone 1
1. Franklin	109108	1. Sangamon	37600
2. Williamson	83117	2. St. Clair	33893
3. Sangamon	73344	3. Madison	17186
4. Macoupin	70813	4. LaSalle	15606

6. Christian	61552	6. Macoupin	10913
7. Saline	57627	7. Williamson	10653
8. Fulton	43578	8. Christian	8864
9. Madison	41714	9. Saline	8670
10. Montgomery	39578	10. Peoria	5896
11. Vermilion	35833	11. Vermilion	5250
12. Randolph	32423	12. Tazewell	5125
13. Peoria	31191	13. Marion	5029
14. Perry	30497	14. Montgomery	4622
15. Jefferson	26949	15. Perry	4426

The acreage of each county in Zone 1 by land use category is listed in Table 6. Complete statistics by township, including Zone 2, are given in Appendix 1. It is beyond the scope of this study to interpret these data as they relate to the operation of the Illinois Mine Subsidence Insurance Fund. The following examples show how these statistics help to recognize the areas

Table 6. Acreage and percentage of category in Zone 1 by county and land use category. (E.g. in Bond County the 506 acres of residential land in Zone 1 represents 27% of the total residential land in the county.

where significant damage from mine subsidence may occur in the future or areas where risk of damage to existing structures is low. In 53 of the 77 counties studied, the percentage of urban land in Zones 1 and 2 was higher (often significantly) than the percentage of the total county area in Zones 1 and 2. For example, less than one percent of Macon County is undermined, consequently mine subsidence coverage is not automatically added to homeowners' insurance policies. However, about 7 percent of the residential land in Macon County is in Zone 1. An additional 5 percent of residential land is in Zone 2. Approximately 7000 housing units are over or adjacent to underground mines and exposed to some subsidence risk.

Macon County also provides an example of the need to examine additional factors that contribute to risk of subsidence. The two mines underlying Decatur used longwall methods in parts of the mines. With this mining method, most subsidence occurs within a few years of mining. The actual risk of subsidence over these mines is much lower than that for other types of mining methods. Table 7 lists counties mines used the longwall method.

Table 7. Counties with longwall mining (based on Guither et al, 1984).

County	Number of Longwall Mines	Total Number of Mines
Bureau	9	47
Christian	1	16
Franklin	6*	35
Grundy	36	204
Hamilton	1*	1
Jefferson	3*	9
LaSalle	22	346

Peoria	1	234
Putnam	4	4
Will	17	48
Williamson	1*	310
Woodford	2	5

*includes mines that used high-extraction-retreat room and pillar methods

In 24 of the 77 counties studied the percentage of the urban land in Zones 1 and 2 was less than the percentage of the total county area in Zones 1 and 2. For example, more than 5 percent of Douglas County was in Zone 1 and 2, but less than 2 percent of the residential area in the county

was in these zones. In a number of these counties there was no urban land in Zones 1 and 2 and the potential damage to existing structures from mine subsidence appeared to be relatively low. Madison County is well-known for its mine subsidence problems. This study found that 23% of the residential land was in Zone 1 (Table 6). However, examination of the map of mines shows that potential mine subsidence is restricted to distinct areas in the county (Appendix 2). Most mines are concentrated in the western half of the county; much of the eastern half has a low subsidence risk.

The urban buffer category helps to identify areas where mined-out area is adjacent to urban land, an indication that subsidence could affect urban expansion. For example, almost 8 percent of Peoria County (including 10 percent of the residential acreage) is in Zone 1. Additionally, 12 percent of the urban buffer land is in Zone 1, indicating that the overall exposure to subsidence risk may increase as the urban areas in Peoria County expand. This statistic is even more dramatic when individual townships are examined. For example, well under 1 percent of the city of Peoria is in Zone 1, but almost 32 percent of the urban buffer in the 3 townships south and west of the city is in Zone 1.

CONCLUSIONS AND RECOMMENDATIONS FOR FURTHER STUDY

Examination of the proximity of mined-out areas to urban land has provided dramatic new views of the exposure of land to potential mine subsidence. Although it is the IMSIF's role to determine the appropriate applications of this information, the information could be useful for reviewing and modifying the insurance rate structure and the geographic areas of and procedures for marketing mine subsidence insurance.

This study identifies a number of areas where past mining activity poses a significant threat to current and future urban development. Detailed mapping of the coal mines in these areas would be beneficial to IMSIF as well as to local businesses, government, and landowners. The goal of this effort should be to map as precisely as possible the extent of mine workings relative to surface features (roads, railroads, houses, streams). The maps or accompanying documentation should indicate the nature of each mine map used (source, date, status, quality), the mining method used, and basic geologic data. This information would streamline the task of investigating mine subsidence insurance claims, alert property owners to the need for mine subsidence insurance coverage, and encourage proper development of undermined lands.

The areas where detailed maps are most needed include the Springfield area in Sangamon County, the Belleville/Collinsville area in St. Clair and Madison Counties, the counties of LaSalle, Macoupin, and Franklin, and the area around the cities of Peoria, Danville and Centralia (Peoria, Vermilion and Marion Counties).

The application of a GIS to the problem of mine subsidence could be expanded in several directions. As more is learned about the factors that contribute to subsidence, we can refine the categories of risk by mapping the factors and adding them into the evaluation. The GIS could be used to help identify these factors by finding spatial correlations between subsidence events and other parameters. Insurance companies may even be interested in using the address matching capabilities of the GIS to merge zone boundaries, street maps, and customer lists to identify the homeowners who should be alerted to the need for mine subsidence insurance coverage.

ACKNOWLEDGEMENTS

Timothy Johnson and Will Hinsman of the Geographic Information Section, Office of Research and Planning, Illinois Department of Energy and Natural Resources, provided the census data for this project as well as advice and assistance on the use of these data.

Margaret Bargh of the Coal Section, ISGS, is responsible for the development and maintenance of the coal mine database and provided advice and assistance on its application to this project.

Appendix 1: Estimated Acreage and Housing Units in Zones 1 and 2 by Township, County, and Land Use Category

This appendix shows the estimated acreage and number of housing units in Zones 1 and 2 by township, county, and land use category. The townships listed here are administrative townships, not land survey townships. Only those townships that have some acreage in Zones 1 or 2 are listed. The location of these townships is shown on the maps in Appendix 2. Though the acreages are listed down to a single digit, this is not meant to imply precision. The estimates of acreages were calculated by overlaying maps from several sources and are subject to the usual inaccuracies inherent in this type of procedure. The figures are believed to accurately represent the relative proportion of acreage in each land use category.

The total number of housing units in each township and county is from the 1980 census. The number of housing units in Zones 1 and 2 was calculated by computer using the land use acreages and the census data. The results of this computation are influenced by the accuracy of the land use data and certain assumptions made about the distribution of housing units within a township. These figures are believed to be reasonable estimates of the relative number of housing units in each Zone.

The first line of data for each township shows the total acreage in that township for each land use category and the total number of housing units in the township. The percentage listed after each acreage in the first line is the percentage of the township represented by that land use category. The next two lines of data for each township show the acreage in each land use category in Zones 1 and 2. The percentage listed after each acreage on these lines is the percentage of that land use category in that zone. For example in Melrose Township, Adams County, the 24 acres of residential in Zone 2 represents 2.2 % of the total acreage of residential land in that township. The last line is the sum of the acreage and housing units in Zones 1 and 2. The estimated number of housing units in Zone 1 of each township of a county is represented graphically in Appendix 2. The county totals follow the same format as the township totals. The total acreages for each land use category in the county may be higher than the sum of the townships listed because they include the acreage in townships that had no acreage in Zones 1 and 2. The Zone 1 acreage totals for each county are represented graphically in Appendix 2.

Appendix 2: Maps and Charts Depicting the Distribution of Mines, Land Use and Housing Units

This appendix contains a map and two charts for each county studied in this project. The maps depict the location of the residential and other urban land use, townships, Zones 1 and 2, and the urban buffer zone. All maps are 1:250,000 scale and use the symbols shown below. Mine boundaries are not delineated because at this map scale they coincide with the Zone 1 boundary.

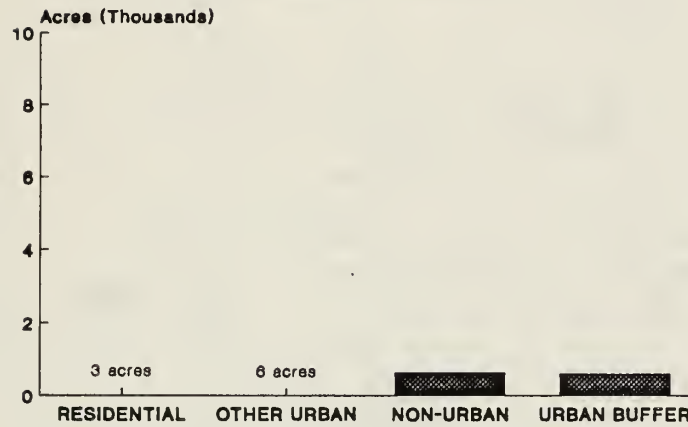

The charts depict selected data from Appendix 1: the total county acreage in Zone 1 in the land use categories and the estimated number of housing units for each township. To facilitate comparisons of charts between counties we have used the same scale for most charts. Different scales had to be used for some counties to accommodate unusually large acreage or housing unit values. Most of the land use charts have a maximum y-axis of 10,000 acres; a few have a maximum of 50,000 acres and one has 100,000 acres. Most of the housing unit charts have a maximum x-axis of 3,000 units; a few have a maximum of 10,000 or 25,000 units.
